CSCI 446: Artificial Intelligence

Markov Decision Processes III

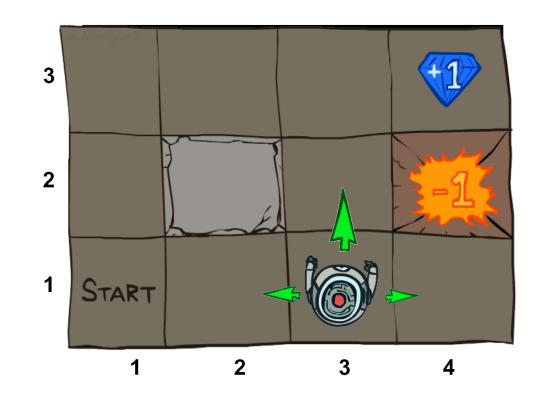

Instructor: Michele Van Dyne

Today

- Policy Methods
 - Policy Evaluation
 - Policy Extraction
 - Policy Iteration
- Double Bandits!!

Example: Grid World

- A maze-like problem
 - The agent lives in a grid
 - Walls block the agent's path
- Noisy movement: actions do not always go as planned
 - 80% of the time, the action North takes the agent North
 - 10% of the time, North takes the agent West; 10% East
 - If there is a wall in the direction the agent would have been taken, the agent stays put
- The agent receives rewards each time step
 - Small "living" reward each step (can be negative)
 - Big rewards come at the end (good or bad)
- Goal: maximize sum of (discounted) rewards

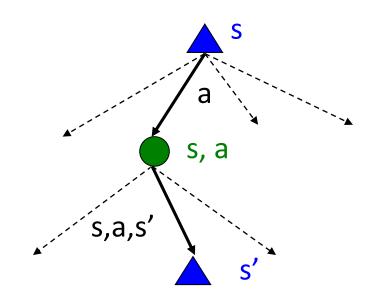

Recap: MDPs

Markov decision processes:

- States S
- Actions A
- Transitions P(s'|s,a) (or T(s,a,s'))
- Rewards R(s,a,s') (and discount γ)
- Start state s₀

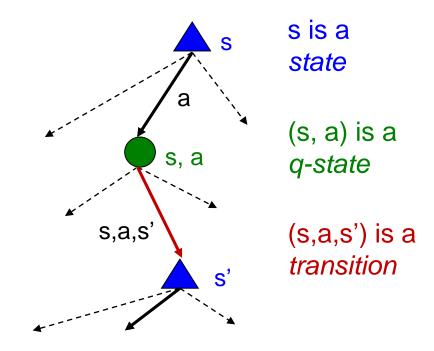

• Quantities:

- Policy = map of states to actions
- Utility = sum of discounted rewards
- Values = expected future utility from a state (max node)
- Q-Values = expected future utility from a q-state (chance node)

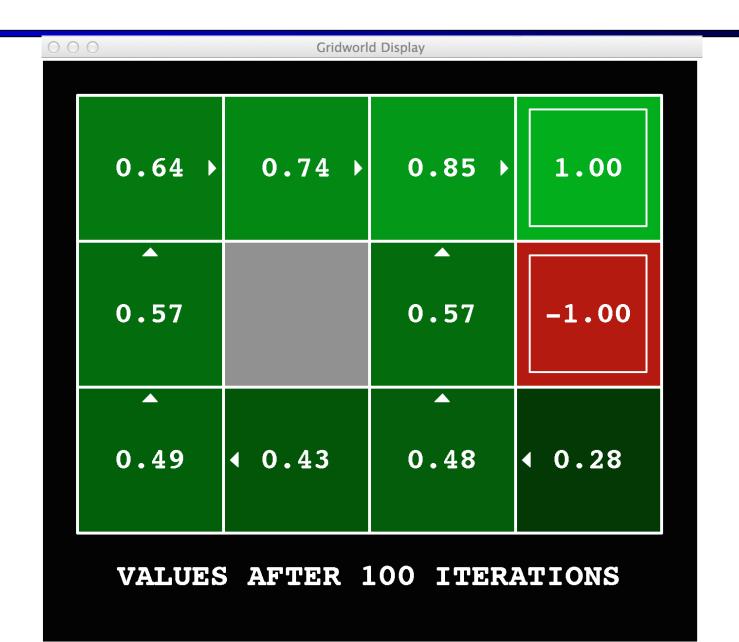

Optimal Quantities

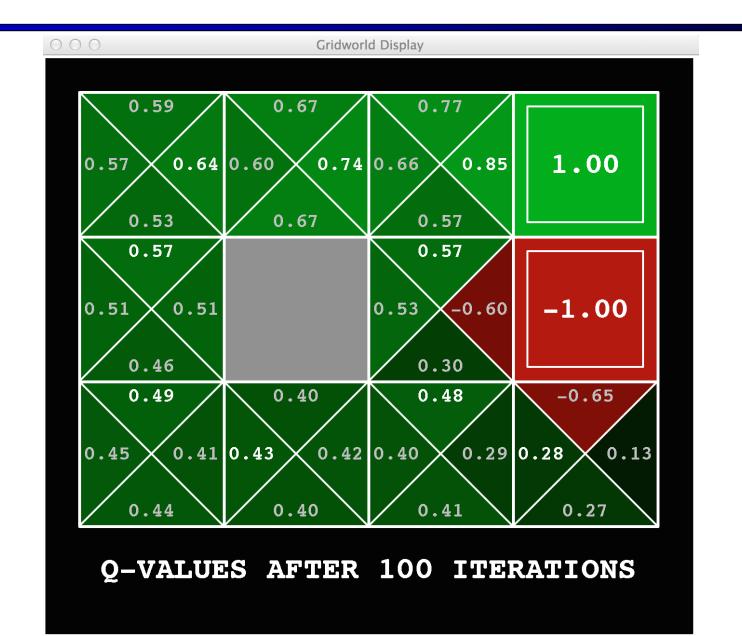

- The value (utility) of a state s:
 - V*(s) = expected utility starting in s and acting optimally
- The value (utility) of a q-state (s,a):
 - Q*(s,a) = expected utility starting out having taken action a from state s and (thereafter) acting optimally
- The optimal policy:
 - $\pi^*(s)$ = optimal action from state s

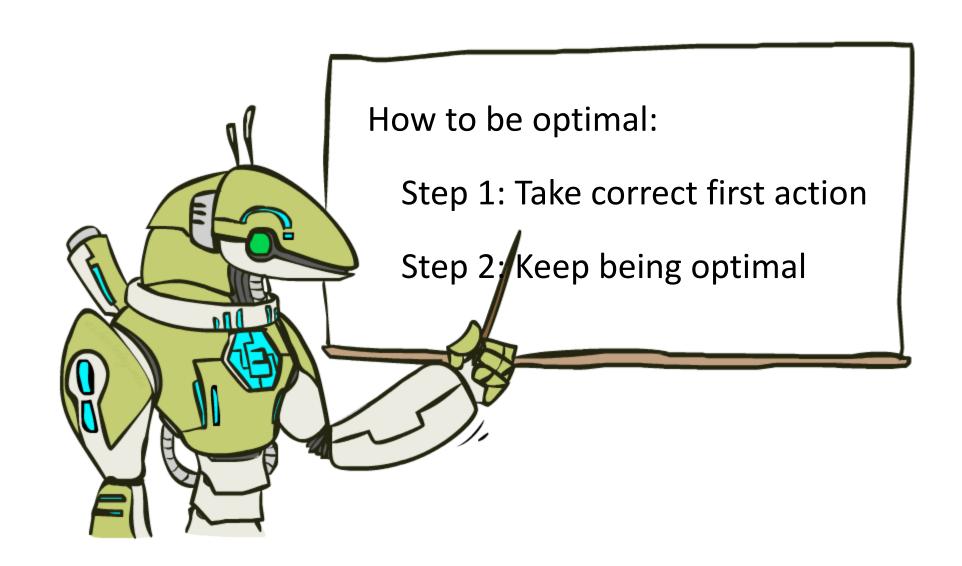

Gridworld Values V*

Gridworld: Q*

The Bellman Equations

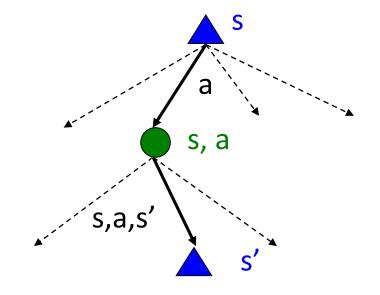

The Bellman Equations

 Definition of "optimal utility" via expectimax recurrence gives a simple one-step lookahead relationship amongst optimal utility values

$$V^{*}(s) = \max_{a} Q^{*}(s, a)$$

$$Q^{*}(s, a) = \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^{*}(s') \right]$$

$$V^{*}(s) = \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^{*}(s') \right]$$

 These are the Bellman equations, and they characterize optimal values in a way we'll use over and over

Value Iteration

Bellman equations characterize the optimal values:

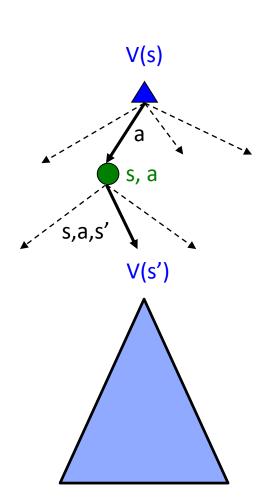

$$V^*(s) = \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^*(s') \right]$$

Value iteration computes them:

$$V_{k+1}(s) \leftarrow \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V_k(s') \right]$$

... though the V_k vectors are also interpretable as time-limited values

Discount Factor, γ = 0.5

S	a	s'	T(s,a,s')	R(s,a,s')
Α	Clockwise	В	1.0	2.0
Α	Counterclockwise	В	0.4	-2.0
Α	Counterclockwise	С	0.6	2.0
В	Clockwise	Α	0.2	0.0
В	Clockwise	С	0.8	-2.0
В	Counterclockwise	Α	0.6	-1.0
В	Counterclockwise	С	0.4	1.0
С	Clockwise	Α	1.0	-1.0
С	Counterclockwise	Α	0.2	0.0
С	Counterclockwise	В	0.8	-2.0

Part 1: What is $V_{k+1}(C)$?

$V_k(A)$	$V_k(B)$	$V_k(C)$
1.900	0.200	0.000

Part 2: What is Q^* (C, clockwise)?

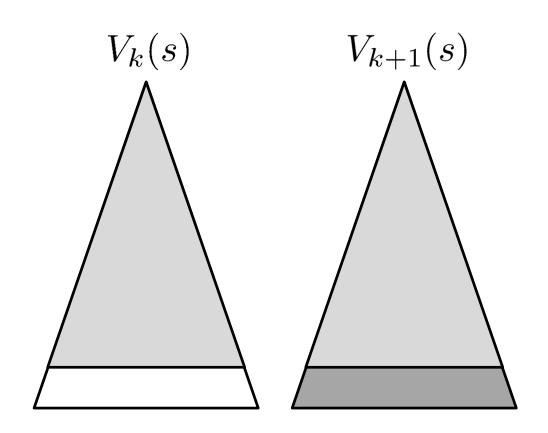

Part 3: What is Q^* (C, counterclockwise)?

Part 4: What is the optimal action from state C?

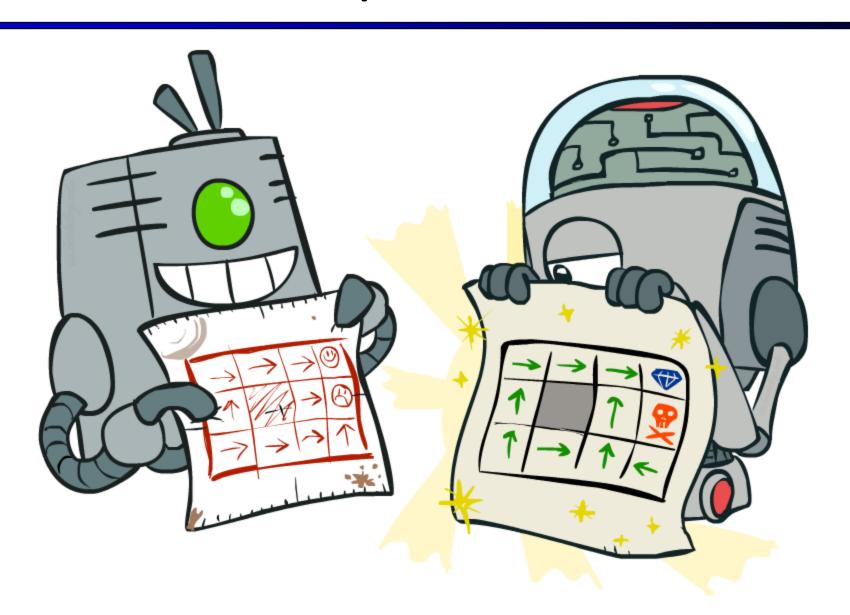

$V^*(A)$	$V^*(B)$	$V^*(C)$
2.250	0.500	0.125

Convergence*

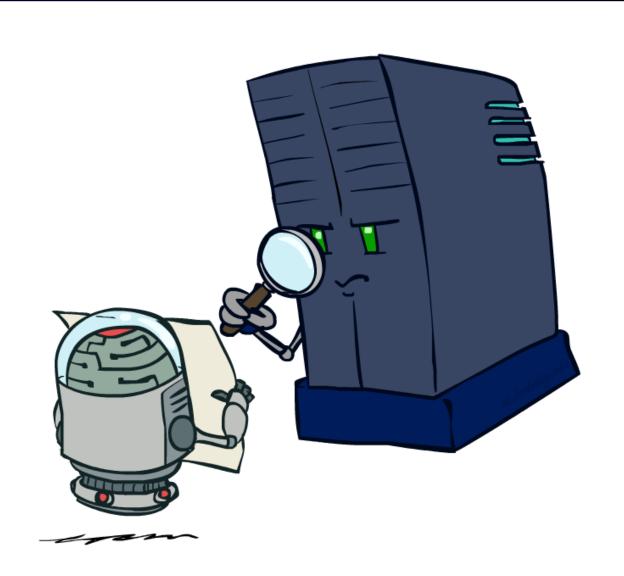

- How do we know the V_k vectors are going to converge?
- Case 1: If the tree has maximum depth M, then V_M holds the actual untruncated values
- Case 2: If the discount is less than 1
 - Sketch: For any state V_k and V_{k+1} can be viewed as depth k+1 expectimax results in nearly identical search trees
 - The difference is that on the bottom layer, V_{k+1} has actual rewards while V_k has zeros
 - That last layer is at best all R_{MAX}
 - It is at worst R_{MIN}
 - But everything is discounted by y^k that far out
 - So V_k and V_{k+1} are at most γ^k max |R| different
 - So as k increases, the values converge

Policy Methods

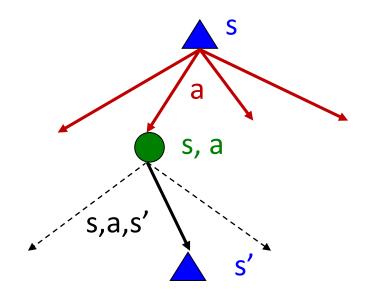

Policy Evaluation

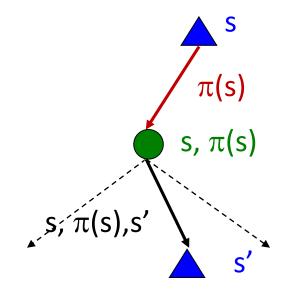

Fixed Policies

Do the optimal action

Do what π says to do

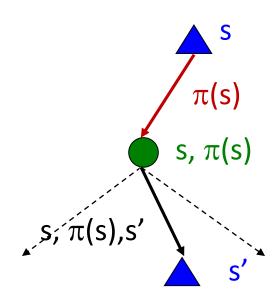

- Expectimax trees max over all actions to compute the optimal values
- If we fixed some policy $\pi(s)$, then the tree would be simpler only one action per state
 - ... though the tree's value would depend on which policy we fixed

Utilities for a Fixed Policy

- Another basic operation: compute the utility of a state s under a fixed (generally non-optimal) policy
- Define the utility of a state s, under a fixed policy π : $V^{\pi}(s)$ = expected total discounted rewards starting in s and following π
- Recursive relation (one-step look-ahead / Bellman equation):

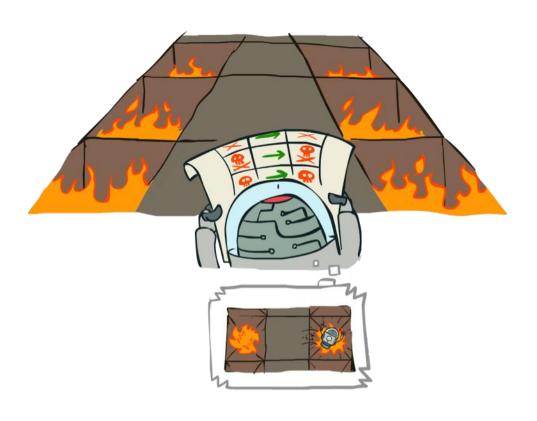

$$V^{\pi}(s) = \sum_{s'} T(s, \pi(s), s') [R(s, \pi(s), s') + \gamma V^{\pi}(s')]$$

Example: Policy Evaluation

Always Go Right

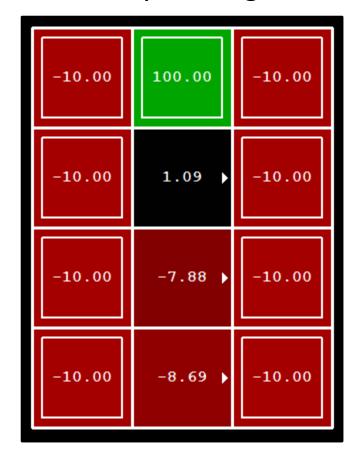

Always Go Forward

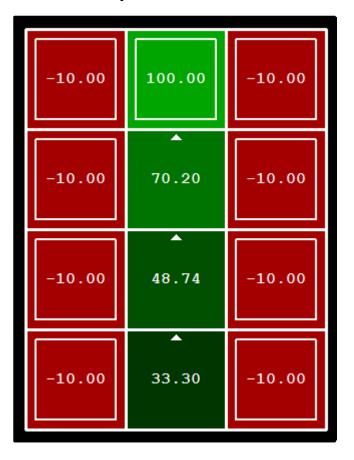

Example: Policy Evaluation

Always Go Right

Always Go Forward

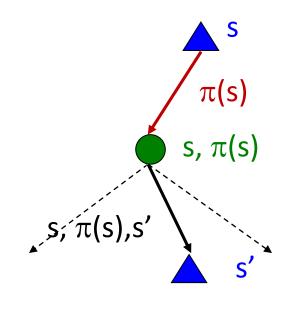

Policy Evaluation

- How do we calculate the V's for a fixed policy π ?
- Idea 1: Turn recursive Bellman equations into updates (like value iteration)

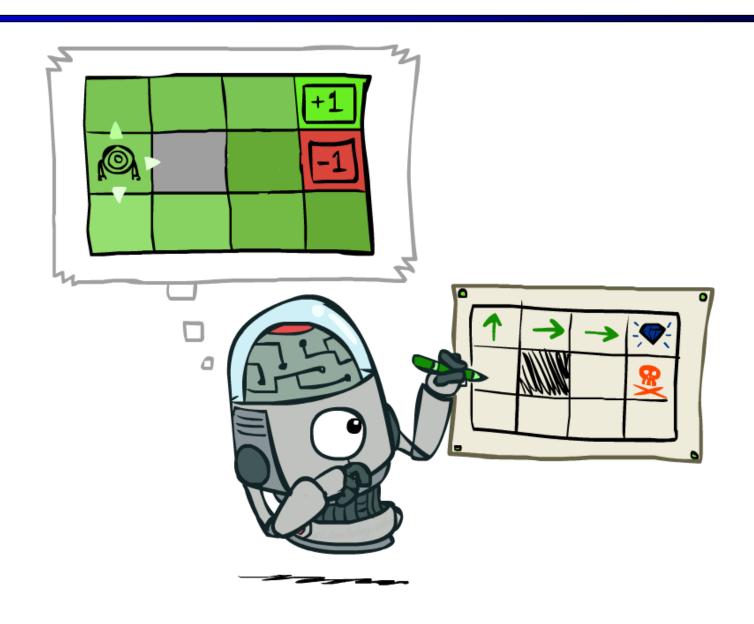

$$V_0^{\pi}(s) = 0$$

$$V_{k+1}^{\pi}(s) \leftarrow \sum_{s'} T(s, \pi(s), s') [R(s, \pi(s), s') + \gamma V_k^{\pi}(s')]$$

- Efficiency: O(S²) per iteration
- Idea 2: Without the maxes, the Bellman equations are just a linear system
 - Solve with Matlab (or your favorite linear system solver)

Policy Extraction

Computing Actions from Values

- Let's imagine we have the optimal values V*(s)
- How should we act?
 - It's not obvious!
- We need to do a mini-expectimax (one step)

$$\pi^*(s) = \arg\max_{a} \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')]$$

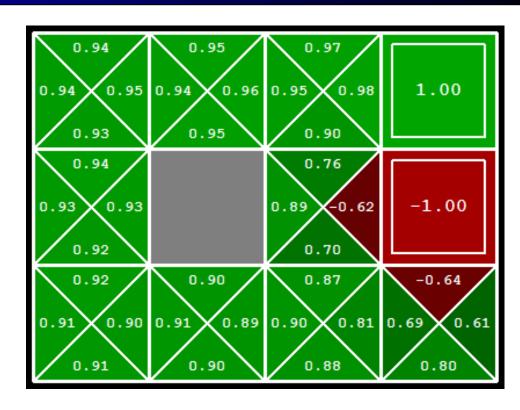

This is called policy extraction, since it gets the policy implied by the values

Computing Actions from Q-Values

Let's imagine we have the optimal q-values:

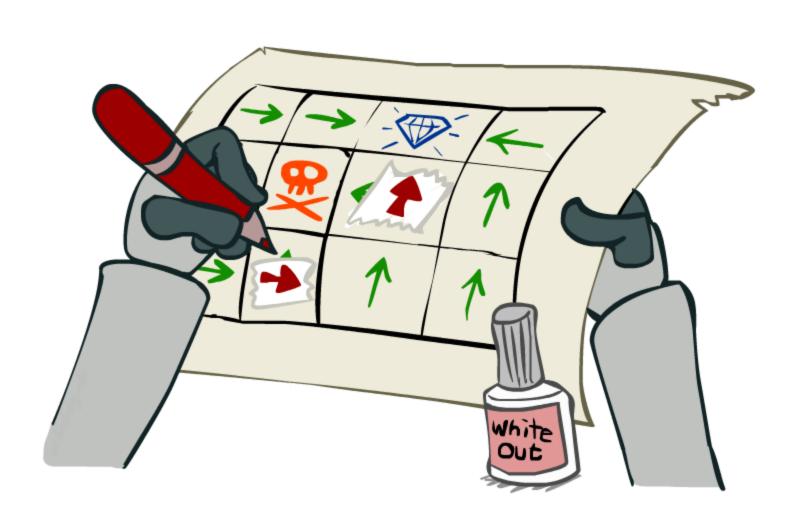

- How should we act?
 - Completely trivial to decide!

$$\pi^*(s) = \arg\max_a Q^*(s, a)$$

Important lesson: actions are easier to select from q-values than values!

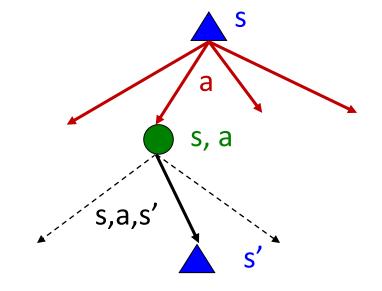

Policy Iteration

Problems with Value Iteration

Value iteration repeats the Bellman updates:

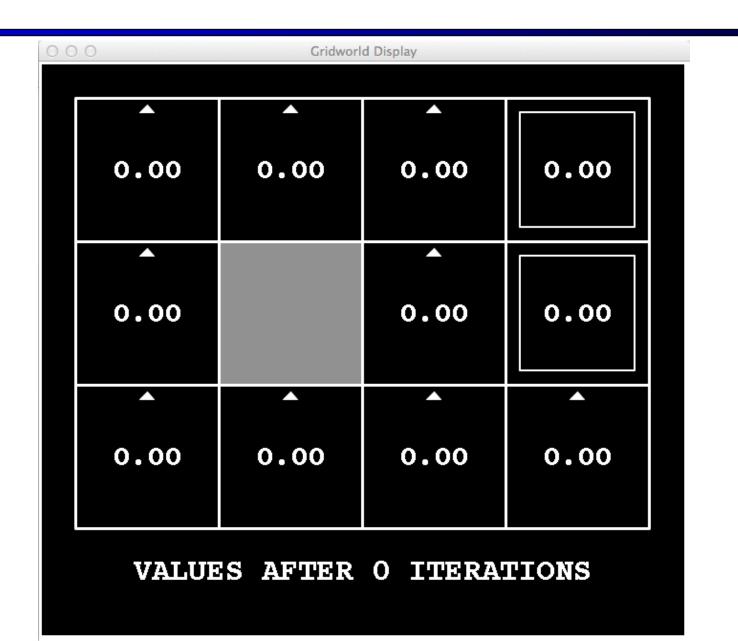

$$V_{k+1}(s) \leftarrow \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V_k(s') \right]$$

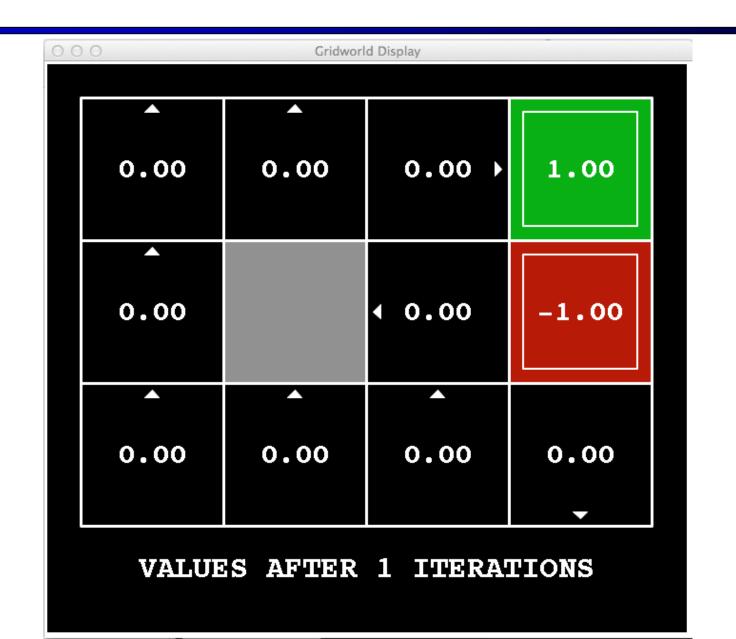

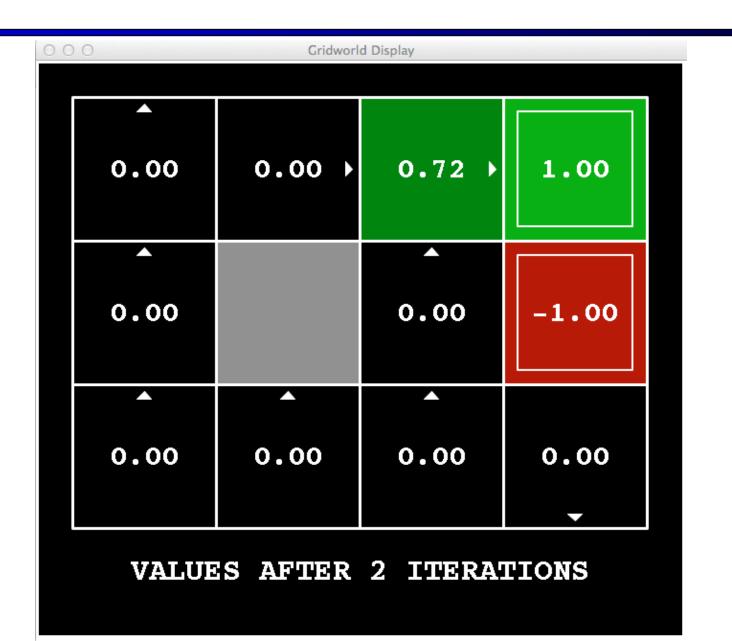

Problem 1: It's slow – O(S²A) per iteration

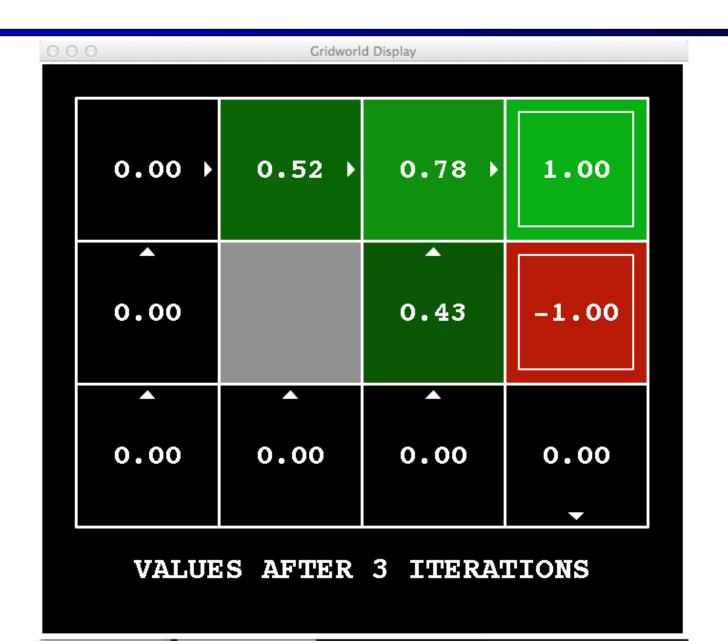

Problem 2: The "max" at each state rarely changes

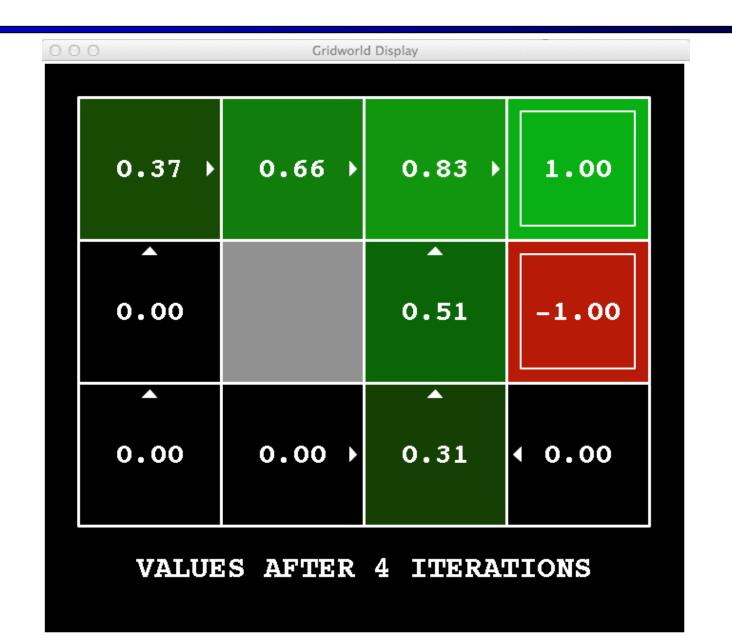

Problem 3: The policy often converges long before the values

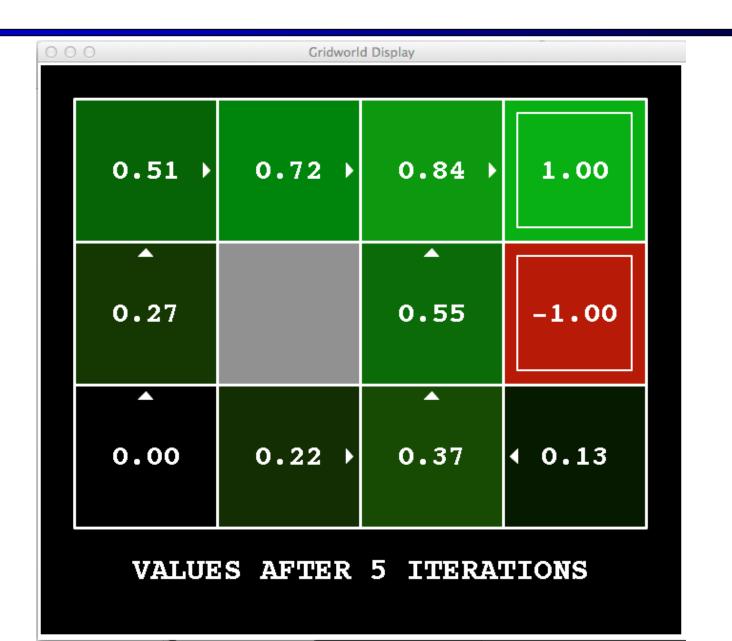

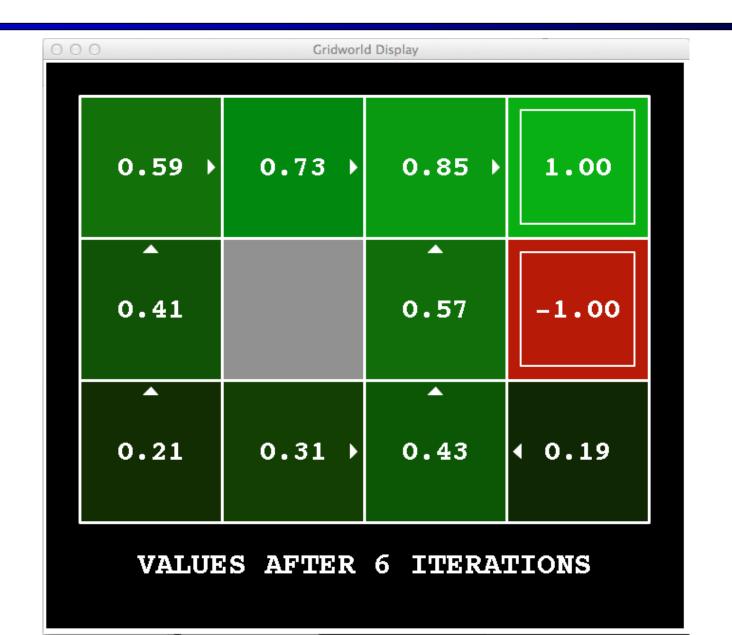

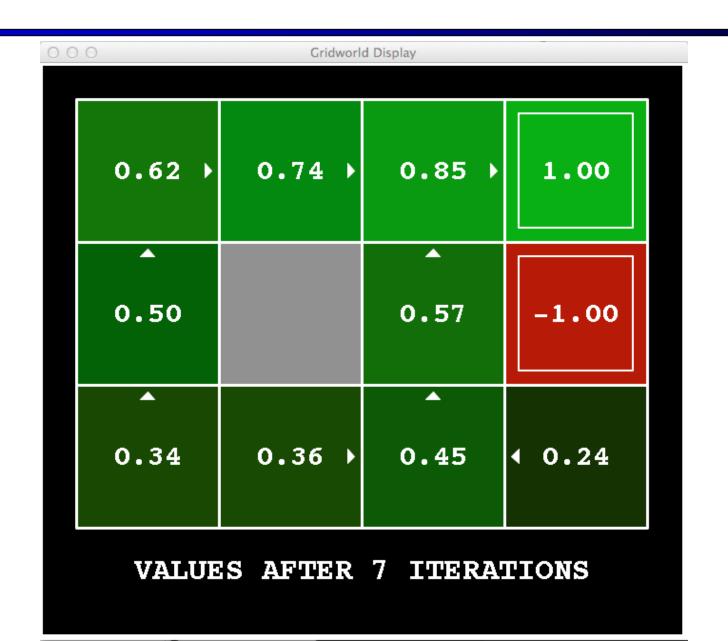

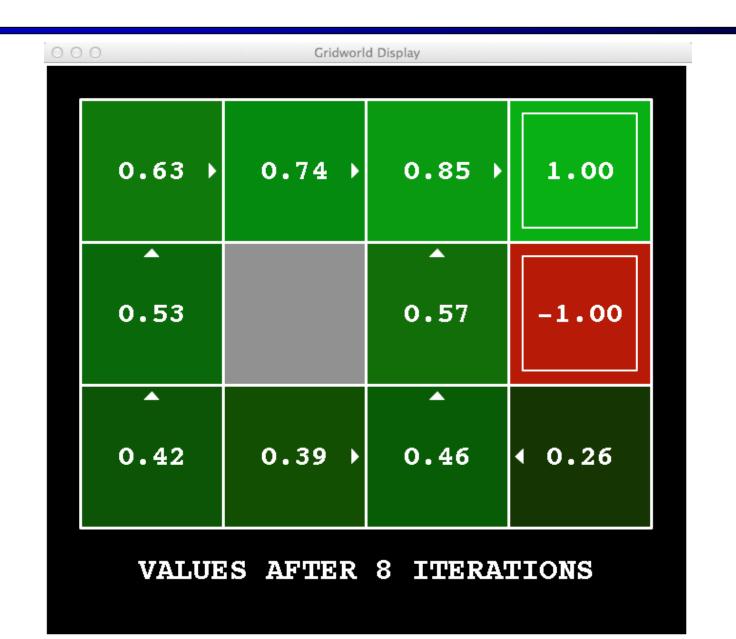

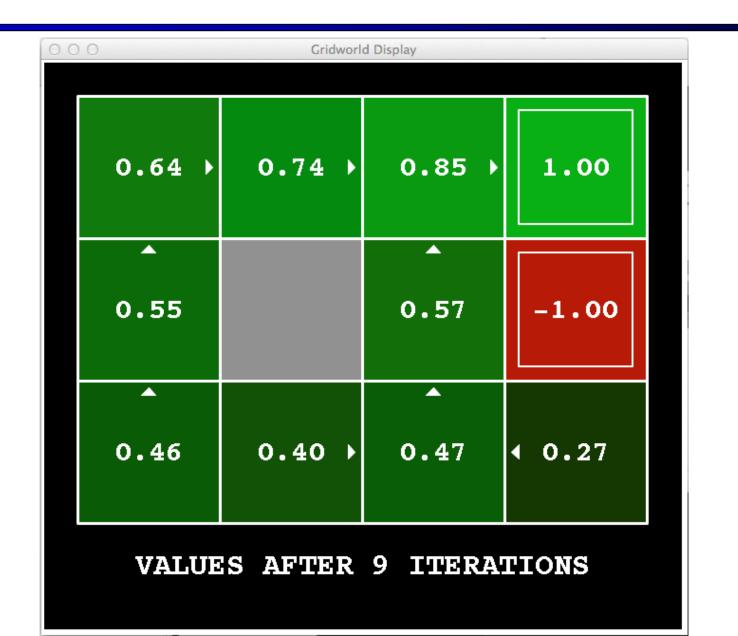

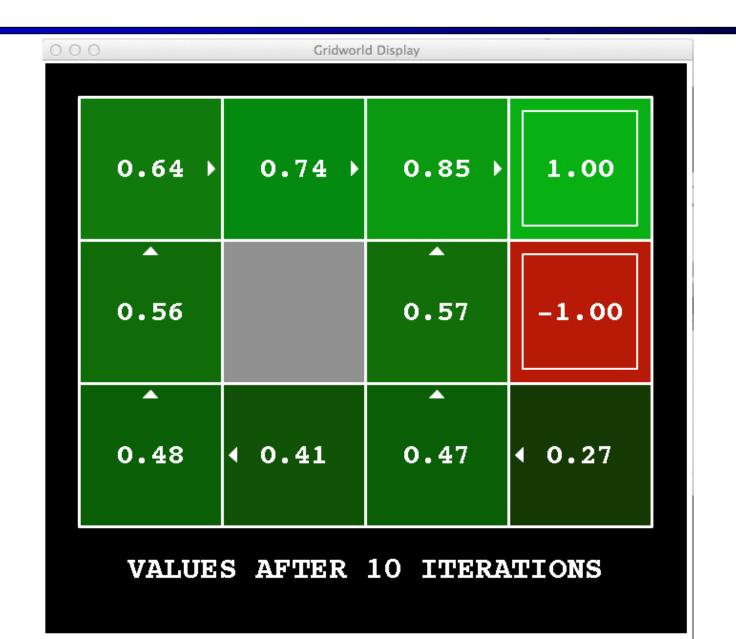

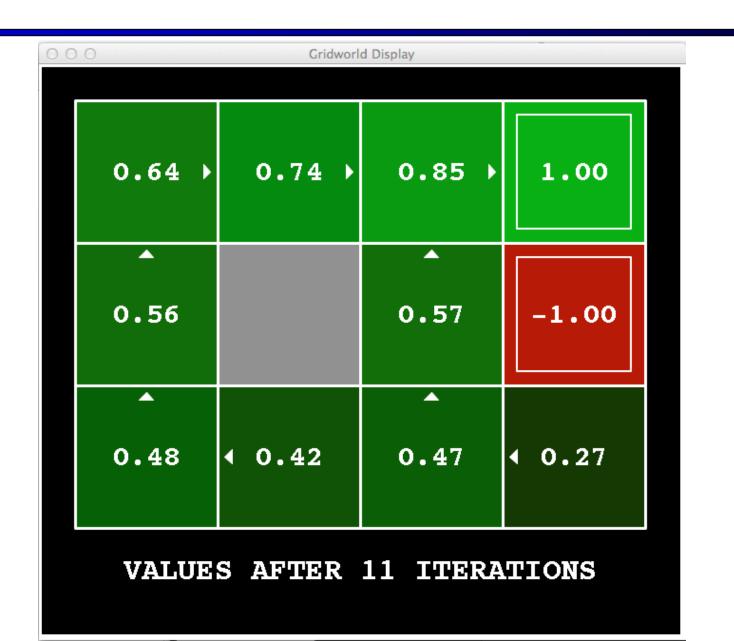

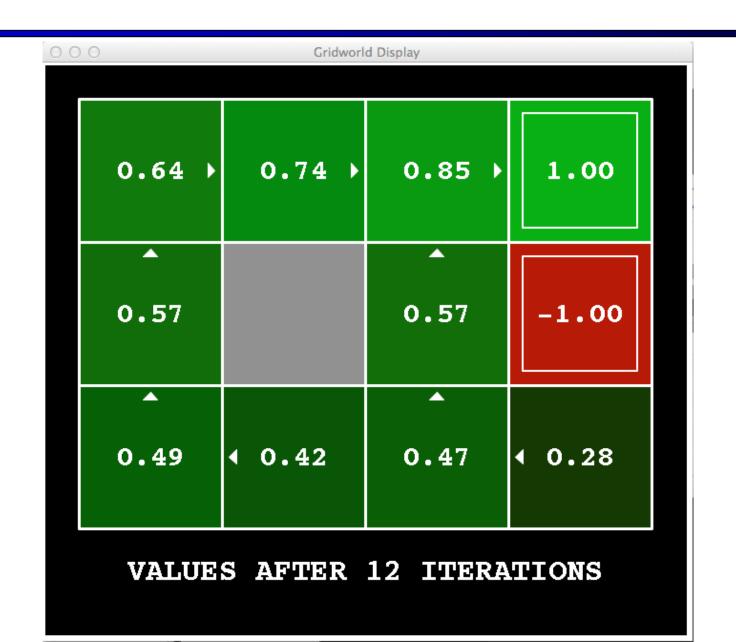

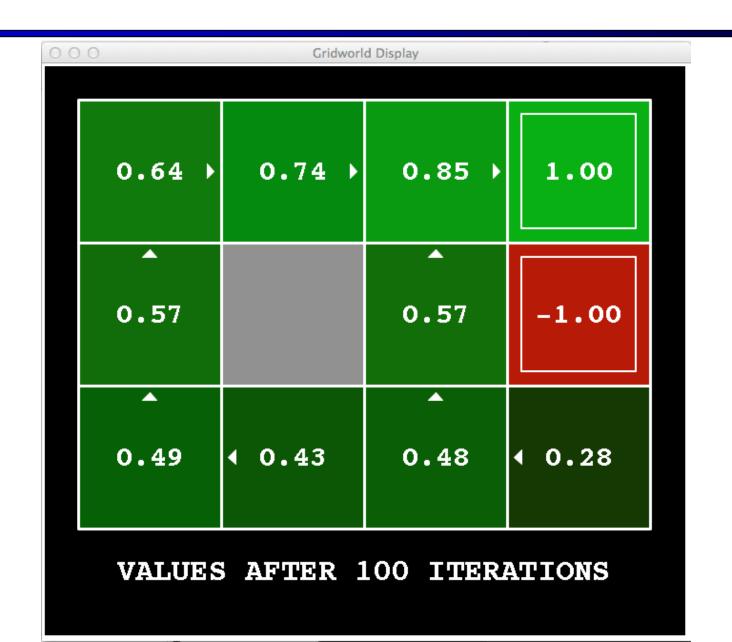

k=12

Noise = 0.2 Discount = 0.9 Living reward = 0

k = 100

Noise = 0.2 Discount = 0.9 Living reward = 0

Policy Iteration

- Alternative approach for optimal values:
 - Step 1: Policy evaluation: calculate utilities for some fixed policy (not optimal utilities!) until convergence
 - Step 2: Policy improvement: update policy using one-step look-ahead with resulting converged (but not optimal!) utilities as future values
 - Repeat steps until policy converges
- This is policy iteration
 - It's still optimal!
 - Can converge (much) faster under some conditions

Policy Iteration

- Evaluation: For fixed current policy π , find values with policy evaluation:
 - Iterate until values converge:

$$V_{k+1}^{\pi_i}(s) \leftarrow \sum_{s'} T(s, \pi_i(s), s') \left[R(s, \pi_i(s), s') + \gamma V_k^{\pi_i}(s') \right]$$

- Improvement: For fixed values, get a better policy using policy extraction
 - One-step look-ahead:

$$\pi_{i+1}(s) = \arg\max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^{\pi_i}(s') \right]$$

Comparison

- Both value iteration and policy iteration compute the same thing (all optimal values)
- In value iteration:
 - Every iteration updates both the values and (implicitly) the policy
 - We don't track the policy, but taking the max over actions implicitly recomputes it
- In policy iteration:
 - We do several passes that update utilities with fixed policy (each pass is fast because we consider only one action, not all of them)
 - After the policy is evaluated, a new policy is chosen (slow like a value iteration pass)
 - The new policy will be better (or we're done)
- Both are dynamic programs for solving MDPs

Summary: MDP Algorithms

So you want to....

- Compute optimal values: use value iteration or policy iteration
- Compute values for a particular policy: use policy evaluation
- Turn your values into a policy: use policy extraction (one-step lookahead)

These all look the same!

- They basically are they are all variations of Bellman updates
- They all use one-step lookahead expectimax fragments
- They differ only in whether we plug in a fixed policy or max over actions

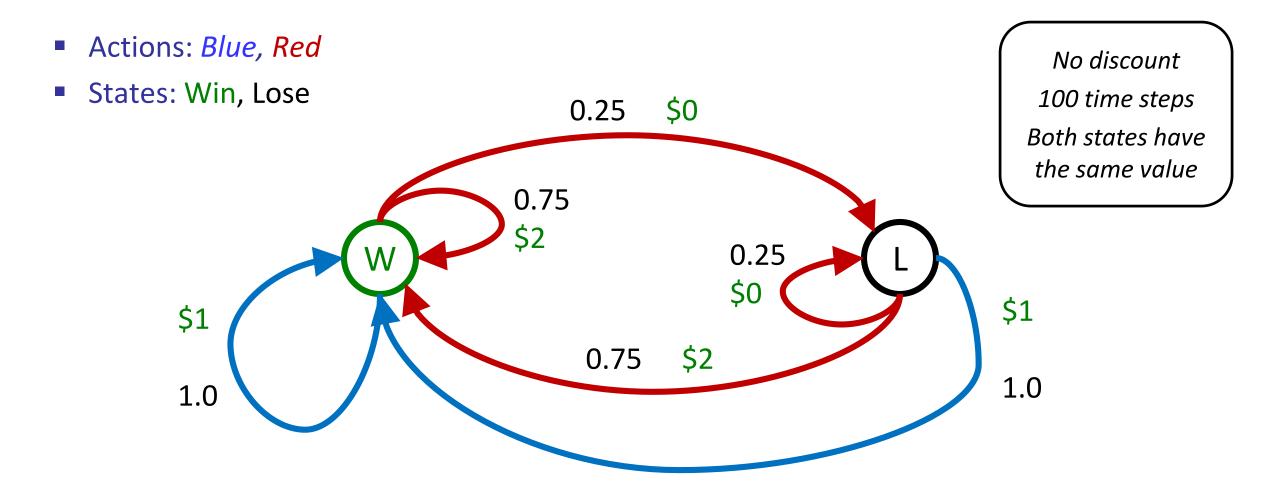

Double Bandits

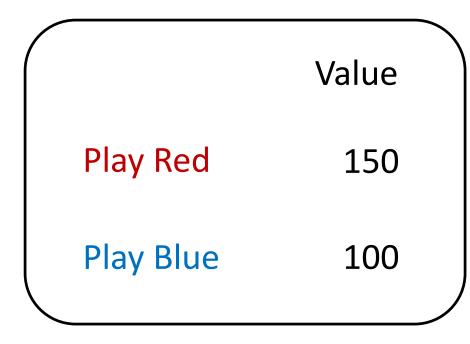

Double-Bandit MDP

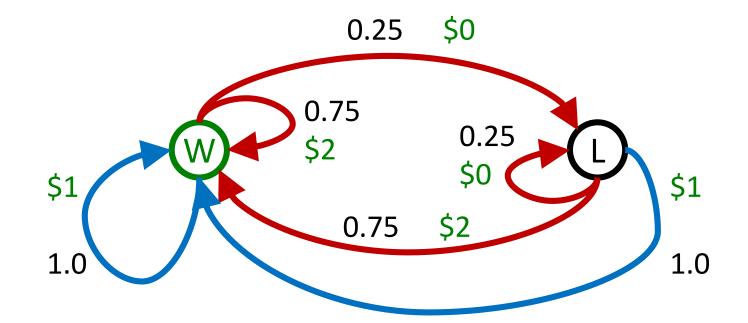

Offline Planning

- Solving MDPs is offline planning
 - You determine all quantities through computation
 - You need to know the details of the MDP
 - You do not actually play the game!

No discount
100 time steps
Both states have
the same value

Let's Play!

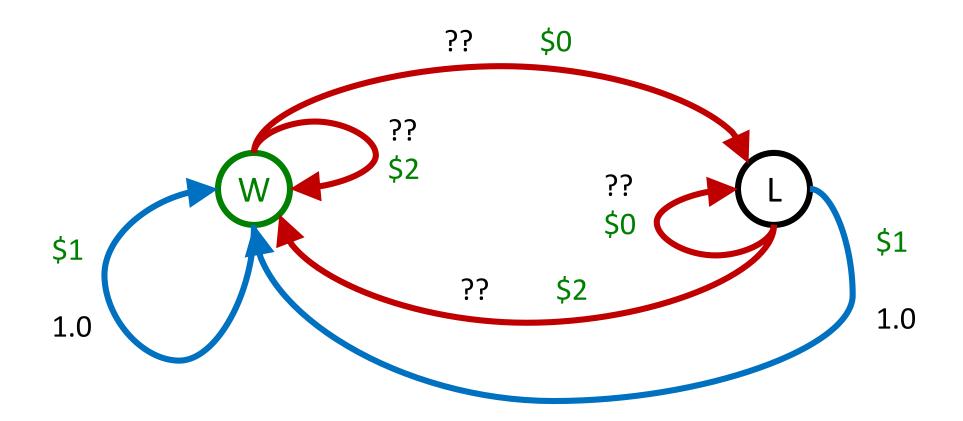

\$2 \$2 \$0 \$2 \$2

\$2 \$2 \$0 \$0 \$0

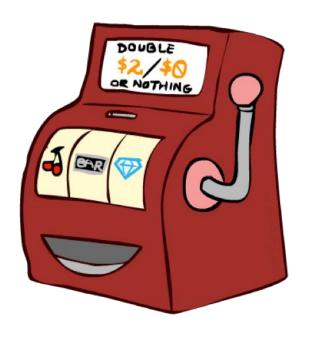

Online Planning

Rules changed! Red's win chance is different.

Let's Play!

\$0 \$0 \$0 \$2 \$0

\$2 \$0 \$0 \$0 \$0

What Just Happened?

- That wasn't planning, it was learning!
 - Specifically, reinforcement learning
 - There was an MDP, but you couldn't solve it with just computation
 - You needed to actually act to figure it out

- Important ideas in reinforcement learning that came up
 - Exploration: you have to try unknown actions to get information
 - Exploitation: eventually, you have to use what you know
 - Regret: even if you learn intelligently, you make mistakes
 - Sampling: because of chance, you have to try things repeatedly
 - Difficulty: learning can be much harder than solving a known MDP
